general

This report presents information on scientists, engineers, and technicians (SET's) in Trade and Regulated Industries in 1982. The data come from the Occupational Employment Statistics (OES) Survey, a Federal/State program producing national, State, and local data on occupational employment by industry for nonfarm wage and salary workers. The Bureau of Labor Statistics (BLS) has primary responsibility for developing survey procedures and providing technical guidance. State Employment Security Agencies implement the survey at State and local levels and prepare current and projected employment statistics for these labor markets. BLS also conducts supplemental surveys in nonparticipating States, and then combines the data from all States into national estimates.

The National Science Foundation (NSF) has enhanced the BLS effort since 1977 by financing full coverage of SET occupations and data collection in nonparticipating States. Thus, the data yield reliable national estimates of the utilization of SET's by private industry. Analysis of this information provides insight into the dynamics of the labor market as SET requirements respond to variations in growth among industries, and to the impact of technology, and other factors, upon industry. Section C of this publication lists analytical reports and statistical data from OES surveys.

technical notes

scope of the survey

The OES survey[1] is conducted in 3-year cycles: manufacturing industries are surveyed the first year; mining, construction, financial, and various service industries in the nonmanufacturing sector are surveyed in the second; and trade, communications, transportation, and public utilities (Trade and Regulated Industries in this report) in the third year. Data in this report, from the 1982 surveys of Trade and Regulated industries, are in Standard Industrial Classification (SIC) codes 40 through 59. The reference dates of the survey were the weeks that included April 12, May 12, or June 12, depending on the SIC of the sample unit. The survey covered all 50 States and the District of Columbia.

method of collection

Schedules for the OES survey were mailed to personnel offices of most sample establishments. Nonrespondents received two additional mailings at 6-week intervals, with telephone follow-ups thereafter. Field personnel visited those companies essential to the survey because such companies have large absolute or relative employment within their industry.

Each industry surveyed received a questionnaire in which occupational detail was limited to primary work activities. Abbreviated survey forms, in which fields of specialization were combined, were sent to small establishments to diminish the reporting burden and to encourage participation. On the questionnaires the specific occupations were grouped under broad Census headings, each with a residual category for work functions not explicitly listed on the survey form. Each respondent was asked to identify any occupations in the residual categories for which employment levels were significant; surveys in subsequent years will be revised to include such jobs explicitly.

[1] A description of the OES Survey can be found in Department of Labor, Bureau of Labor Statistics, Occupational Employment Statistics Handbook (Washington, D.C., Supt. of Documents, U.S. Government Printing Office, April 1979).

limitations on analysis

Data collection methodology in the OES survey introduces several problems that should be taken into account when interpreting these data. First, the OES survey tends to understate requirements in specific fields. Second, this same survey characteristic can be expected to overstate cross-industry differences in staffing patterns: the finer the detail, the more serious the problem. This occurs because an occupation will be listed explicitly on an industry's questionnaire only if it is judged to be a major job class; otherwise, it is put into a residual category.

occupational and industrial classification

The OES survey collects data for approximately 110 SET occupations and uses two classifications systems—the Dictionary of Occupational Titles (DOT) and the 1980 Census of Population. The DOT system is used to develop occupational categories and definitions because its classification scheme is detailed. Summary categories and residual groups are comparable to the broader categories used in the Census.

Industries surveyed were classified according to the 1972 SIC codes. Reporting establishments were categorized on the basis of major product or activity for the previous calendar year.

concepts

An establishment, such as a factory, is the primary sampling unit in the survey. In general, it represents a single physical location and engages primarily in one type of economic activity. When several distinct activities are performed in one location, each is construed as being performed in an individual establishment, assuming that separate payroll records and other criteria are met.

BEST COPY AVAILABLE

This report covers several types of personnel. Full- and part-time workers; workers on paid vacation or on other types of leave; workers on unpaid short-term absence; salaried officers, executives, and staff of unincorporated firms; employees temporarily assigned to other units; and employees for whom the unit is their permanent duty station. Excluded from coverage are proprietors (owners and partners of unincorporated firms), unpaid family workers, and workers on extended leave.

Occupation means the work employees do, rather than the field for which they trained. Skilled personnel are an exception when engaged in the sale of scientific and engineering (S/E) equipment: such personnel are categorized in terms of their fields of specialization. To categorize one as a scientist or engineer requires work at a level of knowledge equivalent to that acquired by completion of a 4-year college course with a major in that field, regardless of whether a college degree was ever obtained. Employees who perform multiple functions are reported only in the job believed to require the highest skill level. Supervisors who spend more than one-fifth of their time doing work similar to that of individuals under their supervision are classified in the occupation most closely related to their work duties.

sampling procedures

The OES survey is a probability sample with a sampling frame based on lists of establishments covered by State Unemployment Insurance (U.I.) systems. Because each cooperating State selects its own sample, the reference date of the sampling frame varies by date when the last sample frame was updated and the survey was conducted. The reference date for sampling in the three States surveyed by BLS for the 1982 survey was the first quarter of 1982.

The survey universe is stratified by industry and size of establishment unit since these characteristics are believed to be primary determinants of occupational staffing patterns. Nine size classes were represented, based on the numbers of people employed: 1 to 3, 4 to 9, 10 to 19, 20 to 49, 50 to 99, 100 to 249, 250 to 499, 500 to 999, and 1,000 and over.

U.I. reporting units with 1 to 3 employees were not sampled in every State. In this instance, units with 4 to 9 employees received larger weights to represent employment in the 1 to 3 size class. Reporting units with 250 or more employees were included in the sample with certainty. Samples for noncertainty size classes were developed to produce State estimates with target relative errors of 10 percent, 15 percent, and 20 percent at one standard deviation for the noncertainty size classes. This was done for groups of SIC's based on averages of occupational rates and coefficients of variation (CV's) from the previous survey of those SIC's for a set of typical occupations. This SIC sample size was allocated to the size classes proportional to size class employment. The sample was selected systematically with equal probability within each State/SIC/area/size class cell.

The States chose from any of three target relative errors in designing their samples. Some States varied the target relative error by SIC. This decreased the survey's cost by decreasing the sample size.

The sample size for the States surveyed by BLS was developed by first determining the sample size required for national estimates in each 2-digit SIC with a target relative error of 10 percent. This was done by averaging CV's and occupational rates for a set of occupations from the previous survey of those SIC's. This national sample size was then allocated to the three nonparticipating States' size class cells proportionally by employment. Such allocation produced a total initial sample size of 239,580 U.I. reporting units.

response

Of the reporting units selected, 228,244 were eligible (i.e., excluding those out of business and out of scope). Usable responses were obtained from 170,698 units. The response rates were 74.8 percent based on units and 73.8 percent based on weighted employment. After the closeout date for national estimates, additional data were received by States and used in preparing State estimates. Response rates in most States were much higher than the response rate used to develop national estimates.

estimation

Weights were determined for the sample units from which usable responses were received. Each weight was composed of two factors. The first was the inverse of the probability of selection. The second was the nonresponse adjustment factor. For questionnaires that were not returned or were otherwise not usable, a reponse adjustment was made to impute for the nonrespondents. For each of the 3-digit State/SIC/size class sampling cells, a nonresponse factor was calculated that was equal to:

$$\frac{\text{Weighted sample employment of all eligible units in sample}}{\text{Weighted sample employment of all responding eligible units}}$$

The sample employments were taken from the sampling frame. If the nonresponse factor in a cell was greater than a predetermined maximum factor—which increased as the number of respondents in a cell increased—the cell was collapsed with other homogeneous cells within an SIC until the factor for the combined cells was not greater than the appropriate maximum factor. If the collapsing procedure terminated (i.e., no more cells were available for collapse) before satisfying the constraint, then the appropriate maximum factor was used. For size classes 1 through 6, homogeneous cells were determined to be other size cells within the SIC and State. For size classes 7 through 9, homogeneous cells were determined to be other State cells within the SIC and size class. The weight for each unit was the product of the nonresponse adjustment factor and probability of selection.

A combined ratio estimate of occupational employment was used to develop the national estimates. The auxiliary variable used was total employment. The estimating formula was:

$$\hat{P} = \sum_i \left(\frac{\sum_r \sum_k w_{rik} p_{rik}}{\sum_r \sum_k w_{rik} e_{rik}} \right) M_i$$

BEST COPY AVAILABLE

Where P = 2-digit industry occupational employment estimate.

i = 3-digit industry within a 2-digit industry,

j = size class,

k = establishment,

w_{ijk} = weight after nonresponse adjustment in ith industry, jth size class and kth establishment,

P_{ijk} = occupational employment in ith industry, jth size class and kth establishment,

e_{ijk} = total employment in ith industry, jth size class and kth establishment, and

M_i = population total value of employment in ith industry

The population value of total employment (Mi) was obtained from the BLS Survey of Employment, Hours, and Earnings.

The standard formula for the sampling variance for a combined ratio estimate is:

$$V(\hat{P}) = \sum_i \sum_j \left(\frac{N_{ij}^2 (1 - f_{ij})}{n_{ij}} \right) (S_{pij}^2 + R_i^2 S_{eij}^2 - 2K_{ij} S_{pij} S_{eij})$$

where $V(\hat{P})$ = variance of $\hat{P}$

i = 3-digit industry within 2-digit industry,

j = size class,

N_{ij} = total number of units in the ith industry and jth size class,

f_{ij} = sampling fraction in the ith industry and jth size class,

n_{ij} = number of sample units in the ith industry and jth size class,

S_{pij} = standard deviation of p within ith industry and jth size class,

R_i = $(\sum_j \sum_k w_{ijk} p_{ijk}) / (\sum_j \sum_k w_{ijk} e_{ijk})$,

S_{eij} = standard deviation of e within ith industry and jth size class, and

K_{ij} = correlation coefficient between p and e within ith industry and jth size class.

The variances for the occupational estimates were estimated using the following formula:

$$\mathrm{Var}(\hat{P}) = \sum_i \sum_j T_{ij} V_{ij}^2$$

where,

$$T_{ij} = \left(\frac{M_{ij} - e_{ij}}{M_{ij}} \right) \cdot \left(\frac{(\sum_k w_{ijk}^2)(\sum_k w_{ijk})}{(\sum_k w_{ijk})^2 - (\sum_k w_{ijk}^2)} \right) \cdot \left(\frac{M_i}{\sum_j \sum_k w_{ijk} e_{ijk}} \right)^2$$

$$V_{ij}^2 = \sum_k w_{ijk} [(p_{ijk} - R_i e_{ijk}) - (p_{ij} - R_i e_{ij})]^2$$

where M_{ij} = benchmark total employment in the ith industry and jth size class,

R_i = $(\sum_j \sum_k w_{ijk} p_{ijk}) / (\sum_j \sum_k w_{ijk} e_{ijk})$, and

e_{ij} = $\sum_k e_{ijk}$,

and all other terms are as defined previously. This formula is almost a computational form of the standard formula, $V(\hat{P})$, already given. One simplifying assumption has been made:

$$W_{ijk} = c_{ij} \text{ for all k in a given ij cell}$$

That is, the weights are equal to a constant C within a given 3-digit industry/size class cell. The total effect of this assumption on the variance estimates was not measured.

reliability of estimates

The estimates developed from the sample may differ from the results of a census of all the establishments in the sample frame. There are two types of errors, sampling and nonsampling, possible in an estimate based on sample data. Sampling error occurs because observations are made only on a sample, not on the entire population. Nonsampling error can be attributed to many sources, e.g., inability to obtain information about all cases in a sample, differences in the respondent's interpretation of questions, inability of respondents to provide correct information, errors made in recording, coding, or processing the data, errors made in estimating values for missing data, and failure to represent all units in the population.

The particular sample used in this survey is one of a large number of possible samples of the same size that could have been selected using the same sample design. Estimates derived from the different samples would differ from each other. The deviation of a sample estimate from the average of all possible samples is called the sampling error. The standard error of a survey estimate is a measure of the variation among the estimates from all possible samples and thus is a measure of the precision with which an estimate from a particular sample approximates the average results of all possible samples. The relative standard error is defined as the standard error of the estimate divided by the value being estimated. The variance is the standard error squared. (In the OES Survey, the term "relative error" is used synonymously with the term "relative standard error.")

The sample estimate and an estimate of its standard error enables one to construct interval estimates with prescribed confidence that the interval includes the average result of all possible samples that could be obtained from the sample design for this survey.

To illustrate, if all possible samples were selected, and each of these were surveyed under essentially the same conditions, and an estimate and its estimated standard error were calculated from each sample, then:

1. Approximately 68 percent of the intervals from one standard error below to one standard error above the derived estimate would include the average value of all possible samples. This interval is called a 68-percent confidence interval.
2. Approximately 90 percent of the intervals from 1.6 standard errors below to 1.6 standard errors above the derived estimate would include the average of all possible samples. This interval is called a 90-percent confidence interval.

BEST COPY AVAILABLE

3. Approximately 95 percent of the intervals from two standard errors below to two standard errors above the derived estimate would include the average of all possible samples. This interval is called the 95-percent confidence interval.
4. Almost all intervals from three standard errors below to three standard errors above the derived estimate would include the average of all possible samples.

An inference that the complete coverage would be within the indicated ranges would be correct in approximately the relative frequencies shown.

For example, suppose an estimated employment total is shown as 5,000 with an associated relative error (relative standard error) of 2 percent. Based on these data, the two-thirds confidence interval is from 4,900 to 5,100 employment, and a conclusion that the average estimate of total employment lies within a range computed in this way would be correct for roughly two-thirds of all possible samples.

The relative errors indicate primarily the magnitude of the sampling error, but do not measure biases in the data resulting from nonsampling error. Efforts were made to reduce the biases arising from errors in recording, coding, and processing the data. The adjustments made for nonrespondents assumed that their characteristics were the same as those of the respondents at a given level. To the extent that this is not true, bias is introduced into the data. The magnitude of these biases is unknown.

Particular care should be exercised in the interpretation of estimates based on a small number of cases, or on small differences between estimates, because of relatively large sampling errors and the unknown magnitude of the biases.

TABLE C-3. SCIENTISTS, ENGINEERS, AND TECHNICIANS IN TRADE AND REGULATED INDUSTRIES AS A PERCENT OF TOTAL EMPLOYMENT IN THE INDUSTRIES, AND THE RELATIVE ERROR: 1982--con.

Water supply (SIC 4940)

Field	Total	Percent of industry employment	Relative error
Total	520	2.48	(1)
Engineers	210	1.01	(1)
Civil	210	1.01	16.62
Scientists	60	.28	(1)
Field unspecified	60	.28	15.22
Technicians	250	1.19	(1)
Drafter	100	.48	14.19
All other engineering technicians	90	.43	(1)
Science technicians	60	.28	19.69

Sanitary services (SIC 4950)

Field	Total	Percent of industry employment	Relative error
Total	800	1.56	(1)
Engineers	530	1.05	(1)
Field unspecified	530	1.05	0.00
Scientists	110	.21	(1)
Field unspecified	110	.21	23.12
Technicians	160	.30	(1)
Drafter	70	.13	37.68
Science technicians	90	.17	39.00

See footnotes at end of table.

TABLE C-3. SCIENTISTS, ENGINEERS, AND TECHNICIANS IN TRADE AND REGULATED INDUSTRIES AS A PERCENT OF TOTAL EMPLOYMENT IN THE INDUSTRIES, AND THE RELATIVE ERROR: 1982--con.

Motor vehicles and auto parts and supplies (SIC 5010)

Field	Total	Percent of industry employment	Relative error
Total	4,280	1.00	(1)
Engineers	1,740	.42	(1)
Mechanical	1,390	.34	26.66
Other, n.e.c.	350	.08	.00
Scientists	640	.14	(1)
Mathematical scientists	80	.01	(1)
Systems analysts	560	.13	16.72
Technicians	1,900	.44	(1)
Computer programmer	600	.14	13.12
Electrical/electronic technicians	1,100	.26	27.32
All other engineering technicians	200	.04	(1)

Furniture and home furnishings (SIC 5020)

Field	Total	Percent of industry employment	Relative error
Total	430	0.37	(1)
Scientists	70	.06	(1)
Systems analysts	70	.06	43.36
Technicians	360	.31	(1)
Computer programmer	130	.11	31.26
Engineering technicians	230	.20	.00

Science Resources Studies Highlights

R&D Funds

	NSF No.	Price
Despite Recession, Companies' Own R&D Funding Rose 13% During 1982	84-314	-----
Non-Federal Funding for Academic R&D Activities Increased at a Faster Pace Than Federal Funding in Fiscal Year 1982	84-307	-----
Federal Academic Obligations Increased by 13% in 1982, 5% in Real Dollars	84-305	-----
Real Growth in Federal R&D Funds Estimated at 12% in 1984--Largest Increase Since Midsixties	84-302	-----
Dollar Value of U.S. R&D Expenditures Overseas Declined in 1982	83-329	-----
Companies Plan Increase in R&D Spending Through 1984	83-327	-----

S/E Personnel

Science and Engineering Employment in Academia Grew 3% in 1983	84-317	-----
Graduate Science/Engineering Enrollment Grew by 2% Between Fall 1981 and 1982, With Computer Sciences, Up 20%, Leading Growth	84-313	-----
One-fourth of Academic Research Equipment Classified Obsolete	84-312	-----
1982 Job Market for New Science and Engineering Graduates About the Same as That of Previous Years	84-310	-----
Industry Reports Shortages of Scientists and Engineers Down Substantially From 1982 to 1983	84-303	-----
Doctorate Production in 1982 Stable in Science/Engineering Fields, But Down in Science and Mathematics Education	83-330	-----
No Change in Science and Engineering Student Quality Seen by 60% of Academic Officials--At Least 25% Improvement	83-322	-----
Growth in Neuroscience May Be Leveling Off	83-314	-----

Detailed Statistical Tables

R&D Funds

Academic Science/Engineering R&D Funds, Fiscal Year 1982	84-308	-----
Research and Development in Industry, 1981: Funds, 1981; Scientists and Engineers, January 1982	83-325	-----
Federal Funds for Research and Development, Fiscal Years 1982, 1983, and 1984, Volume XXXII	83-319	-----

S/E Personnel

U.S. Scientists and Engineers: 1982	84-321	In press
Characteristics of Recent Science/Engineering Graduates: 1982	84-318	-----
Academic Science/Engineering: Scientists and Engineers, January 1983	84-309	-----
Academic Science/Engineering: Graduate Enrollment and Support, Fall 1982	84-306	-----
Science and Engineering Doctorates: 1960-82	83-328	-----
Characteristics of Doctoral Scientists and Engineers in the United States, 1981	82-332	-----

Reports

R&D Funds

Federal R&D Funding by Budget Function: Fiscal Years 1983-85	84-316	-----
Federal Support to Universities, Colleges, and Selected Nonprofit Institutions, Fiscal Year 1982	84-315	-----
Federal Funds for Research and Development, Fiscal Years 1981, 1982, and 1983, Volume XXXI	83-320	$2.50

S/E Personnel

Projected Response of the Science, Engineering, and Technical Labor Market to Defense and Nondefense Needs: 1982-84	84-304	-----
Women and Minorities in Science and Engineering	84-300	-----

Composite

Academic Science/Engineering: 1972-83: R&D Funds, Scientists and Engineers, Graduate Enrollment and Support	84-322	In press
National Patterns of Science and Technology Resources 1984	84-311	-----
A Guide to NSF Science/Engineering Resources Data	84-301	-----
Science and Technology	83-318	-----
Science and Engineering Personnel: A National Overview	82-318	$5.00
